Hematopoietic stem cells (HSCs) give rise to all blood cell types including myeloid and lymphoid lineages. Myeloid cells include monocytes, macrophages, neutrophils, basophils, eosinophils, erythrocytes, dendritic cells, and megakaryocytes or platelets. Lymphoid cells include T cells, B cells, and natural killer cells.

core of most bones. In embryonic development, the red bone marrow is derived from the layer of the embryo called the mesoderm.

Haematopoiesis is the process by which all mature blood cells are produced. It must balance enormous production needs with the need to regulate the number of each blood cell type in the circulation. In

Hematopoietic stem cells (HSCs) represent a heterogeneous population of primitive blood progenitor cells that fall into several different classes. 1,2 Within the human body, they are mainly located in the bone marrow of adults, but are also found in various fetal tissues such as umbilical cord blood, placenta and fetal liver. HSCs are functionally defined by their self-renewal capacity and ...
